Q. How I will define the quality of a software ?

(Suppose I have ₹1000 in hand I went to buy cloths how I will define the quality)

Ans.

If I buy clothes for ₹1000, I evaluate their quality based on:

- **Fabric Quality** – The material should be good and comfortable.
- **Comfort** – The clothes should feel comfortable when worn.
- **Durability** – They should last long and not get damaged easily.
- **Proper Fitting** – The size and fit should match my requirements.
- **Value for Money** – The quality should justify the price paid.

Similarly, as a Software Tester, I evaluate software quality based on:

- **Functionality** – The application should perform all the features and functions as specified in the requirements.
- **Reliability** – The software should work consistently without crashes, failures, or unexpected behavior.
- **Usability** – The application should be easy to understand, navigate, and use for end users.
- **Performance** – The software should respond quickly and handle the expected workload efficiently.
- **Security** – User data should be protected, and unauthorized access should be prevented.
- **Compatibility** – The application should work properly across different browsers, devices, operating systems, and screen sizes.
